Foot-and-mouth disease (FMD) is caused by a virus. There are 7 distinct types. This means that infection with one type will not protect against infection with a different type. New subtypes may suddenly develop, making effective vaccination difficult with new outbreaks. FMD primarily affects cloven-hoofed domestic and wild animals such as cattle, sheep, goats, pigs and water buffalo. It can survive in milk and milk products, frozen bone marrow, and lymph glands.
FMD is a threat to the U.S. because American livestock are naïve and it could have a huge economic impact.

Prior to 1929, the United States had FMD in several states, generally due to the importation of infected animals or their products. This led to restrictions being imposed on importations of animals or their products from infected countries in 1929, many of which are still in effect today. An outbreak in Canada in 1953 was quickly controlled and Mexico was endemic with FMD until then as well. The North American continent has been free of FMD since 1953. Internationally, many countries have endemic FMD and some have had significant outbreaks that are highlighted here. Italy’s 1993 outbreak cost over $130 million, and the 1997 Taiwan outbreak cost roughly $15 billion. Great Britain had documented outbreaks in 1967-68 and 1981 in Hampshire. The outbreak in 2001 was estimate to cost the country £8 billion over a 4 year period.

Diagram of United Kingdom.

FMD is considered by many to be the most economically devastating livestock disease virus in the world. This is largely due to the fact that it is easily transmitted, results in economic losses in animal production, and depopulation (as a means of control) would cost the producer and the government millions, even billions of dollars. The indirect effects of FMD would occur when countries around the world close their doors to our exports of beef, pork, mutton, dairy products, and live animals. This means the United States would have the potential to lose $3.1 billion in beef exports and $1.3 billion in pork exports each year. In a revenue impact analysis done of a FMD outbreak in the U.S. by Paarlberg and others (Potential revenue impact of an outbreak of foot-and-mouth disease in the United States. *JAVMA;* 220,7:988-992), it was estimated that $14 billion would be lost in farm income. Livestock exports would drop $6.6 billion. Another indirect effect is that of consumer fear. Even though FMD is not a risk to humans, consumption of red meat and dairy products could be reduced and estimates include a 20% decline in consumer purchases, causing a loss to farm income of $20.8 billion.

Next we will discuss where FMD is found and how severely it affects animals with the disease.
FMD was found worldwide after WWII. The areas where FMD circulates among animals include Asia, Africa, Middle East and parts of South America. Outbreaks have occurred in Taiwan, South Korea, Japan, Mongolia, Britain, France, and the Netherlands. The Netherlands, North and Central America, Australia and New Zealand have been free of FMD for many years. The World Organization for Animal Health (formally known as the OIE- Office des International Epizootics) has a list of Member Countries that are FMD free countries where vaccination is not practiced. The map depicts those countries by shading them white. Taken from the OIE website on Sept. 16, 2005. http://www.oie.int/Cartes/world/a_Monde.htm For updates to that information, please access www.oie.int/eng/info/en_fmd#Resolution as outbreaks continue to occur and FMD-Free status changes.

It is important to understand that FMD has and is currently occurring in many countries around the world. This map is taken from the Food and Agriculture Organization of the United Nations giving us an accurate assessment of the worldwide impact as of June 29, 2004 from the FAO website http://fao.org/ag/againfo/commissions/en/fmdmaps/maps2003/2003.gif

In animals that have never had FMD, like the United States, sickness may reach 100% but the death rate is generally less than 1%. Younger animals and certain strains of the virus may cause the death rate to increase. Because of the economic impact of this disease, animals are generally euthanized to prevent further spread, but could recover in time.

Transmission primarily occurs by inhaling respiratory aerosols, direct contact with infected animals, oral consumption, or through fomites that are contaminated. Aerosol transmission requires proper temperature and humidity. The FMD virus can survive for 1-2 days in the human respiratory tract, thus potentially spreading to animals. Direct contact with other infected animals or with contaminated biological and hormone preparations can spread FMD. Peak transmission occurs when vesicles rupture. Reproductive spread can occur through infected semen used for artificial insemination.
Transmisión a los animales

- Por vía oral
  - Ingestión de partes de un animal infectado
- Por fomites
  - Botas, vestimenta, herramientas
  - En sangre seca el virus de la FMD sobrevive durante días e incluso semanas

Oral consumption of contaminated animal parts such as meat, milk, bones, glands, and cheese can also spread the disease. Contact with contaminated fomites (non-living objects) such as boots, clothing or tools can also be a source of infection. It can remain active on surfaces for days to weeks and survives drying if it is in a part of blood known as serum.

Different animal species react to FMD in different ways. Sheep and goats are considered maintenance hosts in that they have mild signs which delay diagnosis and allow for aerosol, direct contact spread, and environmental contamination. Sheep can carry the virus in their throat tissue for 4-6 months. Pigs are amplifying hosts in that they concentrate the virus in their respiratory secretions and are much more infective via aerosol transmission. Pigs shed high levels of virus, but for only a short time (not long-term carriers). Cattle are indicator hosts because they most often are the first species to show clinical signs with more severe, rapidly progressing lesions. Cattle can carry the virus in their throat tissue for 6-24 months once exposed or vaccinated with FMD.

Transmisión al ser humano

- Muy rara vez
- Actúa como transmisor hacia los animales
  - Alberga el virus en el tracto respiratorio de 1 a 2 días
  - Botas, vestimenta, vehículos contaminados
  - Se propaga a animales susceptibles
- Ingestión de leche o productos lácteos provenientes de animales infectados

It is very rare for humans to become infected with FMD. Vesicles may appear on the skin at the point of contact with an infected blister from an animal. The most important point to understand is that humans may pick up the virus in a variety of ways and transmit FMD to other animals. As mentioned previously, humans can carry the FMD virus in their respiratory tract for 1-2 days. Also, if their boots, clothing or vehicles become contaminated, they may spread the virus to susceptible animals. Although rare, a person may contract an infection if they ingest milk or dairy products from infected animals.

Animales con FMD

The period of time from exposure to signs of disease (incubation period) for FMD is 2 to 12 days and animals that are in contact with infected animals will generally develop signs in 3 to 5 days. Fever and blisters (vesicles) on the feet, mouth, nostrils, muzzle and teats are the characteristic lesions of FMD. These will eventually progress to erosions which cause the affected animal to have clinical signs associated with the lesioned area. Abortion may occur in adults and death in young animals without any other clinical signs. Animals generally recover in two weeks but secondary infections may lead to longer recovery time. The photo depicts oral erosions on the tongue and lips of a cow with FMD.

Síntomas clínicos

- Lapso de tiempo desde la exposición hasta la aparición de síntomas de la enfermedad: de 2 a 12 días
- Fiebre y vesículas
  - Patas, boca, ollar, hocico, pezones
- Abortos
- Muerte de animales jóvenes
- Recuperación en dos semanas a menos que surjan infecciones secundarias
Síntomas clínicos en bovinos

- Lesiones bucales
  - Vesículas en la lengua, almohadilla dental, encías, región posterior de la boca, ollar, hocico
  - Se transforman en erosiones
  - Exceso de saliva, baba, secreción nasal acuosa

Clinical signs in cattle include mouth lesions such as blisters on the tongue, dental pad, gums, back of the mouth, nostrils or muzzle. These will eventually progress to erosions which cause the affected animal to have clinical signs associated with the lesioned area. This will lead to excess saliva, drooling (due to difficulty in swallowing), and watery nasal discharge. The photo depicts a cow with excess saliva and drooling due to mouth lesions. Photo courtesy of the Gray Book.

Síntomas clínicos en bovinos

- Lesiones en los pezones
  - Disminución de producción de leche
- Lesiones en las pezuñas
  - Intradactilares
  - Parte superior de la pezuña
  - Cojera
  - Renuencia a moverse

Teat lesions can occur and cause a decrease in milk production. Hoof lesions between the toes and on the top of the hoof are also common leading to lameness and a reluctance to move. Photo depicts ruptured blisters at the end of a bovine teat, from the Gray Book.

Síntomas clínicos en cerdos

- Lesiones en las pezuñas
  - Más graves que en los bovinos
  - Parte superior de la pezuña, talón, lesiones intradactilares
  - Cojera
  - Vesículas en la trompa
  - Vesículas bucales menos comunes
  - Es raro que exista baba

Pigs have more severe hoof lesions than cattle with blisters at the top of the hoof, heel and between the toes. Blisters are often seen on the snout but mouth lesions are not as common or less severe than in cattle if they do occur. Drooling is rare in pigs because of this. Top photo depicts severe hoof and leg lesions on a pig with FMD (from USDA http://www.usda.gov/oc/photo/01cs0008.htm) and the lower picture is of lame pigs due to their hoof lesions (Gray Book).

Síntomas clínicos en borregos y cabras

- Síntomas leves (en caso de presentarse)
  - Fiebre
  - Lesiones bucales
  - Cojera
- Dificultan el diagnóstico y la prevención

Since sheep and goats are referred to as a maintenance host, fever, mouth lesions and lameness occur but are very mild and sometimes are not detected. This makes it difficult to diagnose and prevent the spread of disease to other species.

Enfermedades vesiculares

- La FMD es una de las cuatro enfermedades que ocasionan vesículas (aftas)
- Dos de ellas afectan a los bovinos
  - La FMD y la estomatitis vesicular
- La única manera de distinguirlas es mediante pruebas de laboratorio - ¡Comuníquense con el médico veterinario!

FMD is one of four vesicular (blister) causing diseases. Cattle can be affected by two of them (FMD and Vesicular Stomatitis). The only way to tell the difference between the two diseases is to run laboratory tests – call the veterinarian!
Clinically, all vesicular diseases produce a fever with blisters (vesicles) that progress to erosions in the mouth, nostrils, muzzle, teats and feet. A person cannot tell the different types of vesicular diseases apart just by looking at them, especially in swine as this chart shows, and diagnosis can only be made through testing for a specific virus. Any disease with blisters (vesicles) and fever should warrant an immediate phone call to your veterinarian.

If you suspect a blister-like (vesicular) illness like FMD in your animals, call your local veterinarian immediately and stop all animal movement.

FMD infection in humans is not considered a public health concern. Since 1921, there have only been 40 human cases that were isolated and typed on three continents (Europe, Africa, South America).

There are various prevention and control methods that can be applied to foot-and-mouth disease and those will be discussed next.

The USDA (United States Department of Agriculture) has upgraded the safeguarding measures in place to prevent introduction of FMD into the U.S. The USDA APHIS (Animal and Plant Health Inspection Service) has strict import restrictions in place to prohibit importation of live ruminants, swine and their products from FMD-affected countries. Government officials at ports of entry continue to monitor travelers and their belongings that have returned from an FMD area. There are 450 foreign animal disease diagnosticians (FADD) employed to investigate suspicious lesions and other unusual symptoms that private veterinary practitioners alert them to. Several states have also been involved in training exercises regarding actions to take if FMD is introduced. Additionally, APHIS has a federal plan in place should it occur on U.S. soil.
### Prevención: a nivel nacional

- 450 expertos en diagnóstico de enfermedades animales exóticas (FADD) investigan lesiones sospechosas
- Planeación / ejercicios de capacitación a nivel estatal

---

### Prevención: en la explotación agropecuaria

- Limiten el acceso a su explotación agropecuaria
- Coloquen avisos para informar a los visitantes acerca de las políticas

---

### Prevención: en la explotación agropecuaria

- Monitorean el tránsito y a los visitantes
- Lleven puesto equipo de protección personal en las áreas de los animales
  - Overoles, botas, cascos limpios
  - Desinfecten las botas
  - Lávense las manos

---

### Prevención: en la explotación agropecuaria

- Restrinjan o detengan la movilización de animales
  - Para evitar que la enfermedad se propague
  - Pongan en cuarentena por un lapso de 30 días a los animales nuevos o que están de regreso
  - Eviten el contacto con animales que deambulan libremente
  - Fauna silvestre, roedores, perros, gatos

---

The USDA (United States Department of Agriculture) has upgraded the safeguarding measures in place to prevent introduction of FMD into the U.S. The USDA APHIS (Animal and Plant Health Inspection Service) has strict import restrictions in place to prohibit importation of live ruminants, swine and their products from FMD-affected countries. Government officials at ports of entry continue to monitor travelers and their belongings that have returned from an FMD area. There are 450 foreign animal disease diagnosticians (FADD) employed to investigate suspicious lesions and other unusual symptoms that private veterinary practitioners alert them to. Several states have also been involved in training exercises regarding actions to take if FMD is introduced. Additionally, APHIS has a federal plan in place should it occur on U.S. soil.

Producers should implement and follow strict, complete biosecurity protocols on U.S. livestock production facilities as their best means of prevention. See the FMD Prevention Practices handout for specific guidelines on protecting your facility from FMD. Biosecurity protocols should include steps such as limiting access to only personnel necessary for the function of the farm. Signs should be posted at the farm entrance to inform visitors of biosecurity policies, such as the one pictured here (graphic design by Clint May, CFSPH). All traffic (vehicle, people and animals) should be closely monitored and recorded in a log book. Clean clothing (coveralls, hats, boots) should be worn when accessing animal areas. These materials should be disinfected or removed and disposed of following the procedure to prevent cross contamination between different areas of your farm. Additionally, hands should be washed with soap and water after contacting animals to prevent spread of disease to animals or humans.

Producers should implement and follow strict, complete biosecurity protocols on U.S. livestock production facilities as their best means of prevention. See the FMD Prevention Practices handout for specific guidelines on protecting your facility from FMD. Biosecurity protocols should include steps such as limiting access to only personnel necessary for the function of the farm. Signs should be posted at the farm entrance to inform visitors of biosecurity policies, such as the one pictured here (graphic design by Clint May, CFSPH). All traffic (vehicle, people and animals) should be closely monitored and recorded in a log book. Clean clothing (coveralls, hats, boots) should be worn when accessing animal areas. These materials should be disinfected or removed and disposed of following the procedure to prevent cross contamination between different areas of your farm. Additionally, hands should be washed with soap and water after contacting animals to prevent spread of disease to animals or humans.

If FMD is reported in the U.S., you can protect your farm by restricting or disallowing movement of your animals off or onto your farm. If animals have been newly introduced or recently returned (e.g., from a show) to your farm, they should be quarantined in an area away from other animals for a period of at least 28-30 days. These animals could be infected with a disease but have not developed signs of illness. By allowing this time period, you can prevent spread of a disease to the remainder of your herd from an ill animal. Although difficult, prevent contact of your herd with other free-roaming animals such as wildlife, rodents or even domestic animals like dogs or cats that could spread disease between farms.
Previsión: en la explotación agropecuaria

- Aprendan a reconocer los síntomas de la FMD
- Monitoren a los animales rigurosamente y frecuentemente
- Aíslen de inmediato a cualquier animal enfermo
- Pónganse en contacto con el médico veterinario encargado de sus animales

The best way to prevent the spread of FMD is rapid detection. This will require close and frequent monitoring of your herd. Other diseases can look similar to FMD, so it is important to immediately isolate animals showing signs of illness or acting unusually and contact your herd veterinarian.

Control

- Desinfección
  - Eliminen toda materia orgánica
  - Estieroles, lodo, alimento
  - Utilicen la concentración adecuada
  - Dejen en contacto el desinfectante durante el tiempo adecuado
  - Vehículos, calzado, equipos

In order to control FMD, proper disinfection of all contact premises and infected materials is necessary. Preparing disinfectants for the farm entrance, vehicles, and people is imperative in preventing the spread. An essential step in effective disinfection is to remove all organic matter (manure, feed, dirt, etc.) prior to application of any disinfectants. Most disinfectants are inactivated by organic material. Additionally, this debris can allow microorganisms “hiding” from the action of disinfectants. Always read the label instruction to determine to concentration needed. More is not always better. Another often overlooked step is to allow for proper contact time after application of the disinfection solution. The chemicals need time to do their job. Cleaning and disinfection of vehicles, equipment, footwear, clothing is essential to minimize the spread of FMD. Photo courtesy of: Danelle Bickett-Weddle, DVM, ISU

Selected disinfectants have been approved by the EPA and USDA for use against the FMD virus. Many of them have safety issues and concerns and should be used with caution. In the event of an FMD outbreak, the best disinfectant of choice will likely be determined by animal health officials. To protect your farm, some of these solutions may be used for preventive purposes. As with all chemicals, always read the label directions and mix the concentration appropriate for your purposes. Wear gloves and goggles to avoid damage to your skin and eyes while mixing or applying most disinfectants.

Control

- No existe ningún tratamiento
- Cuidados de apoyo a los infectados
- Un brote en los EE.UU. podría tener como consecuencia
  - La cuarentena
  - La eutanasia
  - La destrucción
- Vacuna disponible
- Decisión difícil

Currently there is no treatment for FMD as it is a virus. Supportive care may be provided to those animals afflicted with the disease, but due to the grave economic impact, animals will likely be quarantined, euthanized, and disposed of once they are found infected. Vaccines are available for use in some countries, but in the U.S. this may be a difficult decision.
Why don’t we vaccinate for FMD? There is no need to vaccinate against a disease that animals have not had in this country since 1929. However, we may need to do so during an outbreak to contain it. There are implications to vaccinating animals. First, our international trade status would be in jeopardy as we couldn’t claim FMD-free status. To earn FMD-free status, the OIE health code requires a 3-month waiting period after they slaughter their last positive animal, given ongoing surveillance through testing has occurred throughout the disease monitoring process. Next, annual re-vaccination would be required to maintain immunity and this is very costly and time consuming. It would be necessary to vaccinate against all 7 varieties of the virus. Finally, the FMD vaccine does not protect against getting the infection, it just lessens the outcome of the disease. So if a vaccinated animal came in contact with the virus, it could harbor it for months or years in its respiratory tract and shed it to others. This false sense of security of “vaccinated animals” could do more harm than good.

Resources

The 1-866-SAFGUARD (723-48273) is a toll-free hotline with recorded messages for international travelers.
Agradecimientos

La elaboración de esta presentación fue financiada con recursos aportados por la Risk Management Agency del USDA al Center for Food Security and Public Health de la Iowa State University.
