S 1	Hidropericardio/Cowdriosis	Heartwater disease is caused by <i>Ehrlichia (formerly Cowdria)</i> <i>ruminantium</i> (air-lick-EE-ah ROO-mi-NAN-tium) is a rickettsial
i	Ehrlichia ruminantium	bacterium - it lives in cells but is different than a true bacterium. The
d e	- Rickettsia - Hallada en los vasos sanguíneos de	organism initially reproduces in white blood cells (macrophages), then invades and multiplies in blood vessel cells, especially in the brains of
4	animales infectados • Especialmente en el	ruminants. This rickettsia causes the blood vessels to "leak" which is
4	cerebro de rumiantes • Ocasiona "filtraciones" – No sobrevive mucho tiempo	why it has the name heartwater disease- fluid leaks out and fills the sack around the heart. The organism is considered an intracellular parasite
	fuera del hospedero	and cannot survive outside a living host for more than few hours at room temperature. Photo: Brain smear from a goat showing colonies of <i>C</i> .
		<i>ruminantium</i> as the granular blue areas in the cytoplasm of the capillary endothelial cells. From
S		www.vet.uga.edu/vpp/gray_book/photos/pages/061.htm. Heartwater is a threat to the U.S. for several reasons. There is a risk of
1		introduction of the disease through infected ticks or of infected ticks on
i d		imported wildlife. Additionally, a carrier state of the disease has been discovered in several wild animal species that have been imported to the
e	Importancia	U.S. Finally, two tick species indigenous to the U.S. have been shown
5		experimentally to serve as vectors for heartwater.

The first historic identification of heartwater was made in sheep in South Africa in the 1830's. In 1898, heartwater was found to be spread experimentally by injecting blood from diseased animals into susceptible animals. The tropical bont tick (Amblyomma variegatum: amblee-OHMah vahr-ee-GAY-tum) was confirmed as a vector of the disease in South Africa in 1900. The causative agent was found in the tissues of infected animals and ticks by Cowdry in 1925 which later led to the name of the rickettsial organism, Cowdria ruminantium, in 1947. The first reported occurrence of the disease in the Western hemisphere was in 1980 in Guadeloupe, one of the Caribbean Islands. Since then it has gradually spread to as far north as Puerto Rico, southwards to Barbados and St. Vincent. The potential for the tropical bont tick, and thereby heartwater, to be introduced into the U.S. was demonstrated in 1992 when a cattle egret, banded in Guadeloupe (Caribbean), was found in the Florida Keys. Also, in 1997, the same tick species was found on a traveler to the Caribbean upon her return to Florida.

Heartwater is a serious constraint to livestock development in much of sub-Saharan Africa. In an assessment of the economic impact of heartwater and its control in Zimbabwe (Preventive Veterinary Medicine 1999; 39:173-189), the estimated total annual national losses due to heartwater were U.S.\$5.6 million. Losses in commercial systems were 25 times greater than losses in the communal system. The greatest components of economic loss were control (acaricide - used to kill ticks) costs (76%), followed by milk loss (18%) and treatment cost (5%). Heartwater is a serious threat to the United States considering the presence of the disease in the Caribbean and the proximity to the southern coast of the United States. Migratory birds, especially cattle egrets (Bubulcus ibis), have been demonstrated to fly from the Caribbean to Florida. Additionally, U.S. ruminant populations are naïve, and therefore more susceptible to the severe form of the disease. It has been estimated that between 40% and 100% death rate in the cattle population will be recorded if heartwater enters the United States.

Next we will discuss where heartwater can be found and how severely it affects animals with the disease.

Heartwater occurs where its tick vectors are present. The disease is constantly present (endemic) in Africa and the Caribbean islands. Carrier wildlife in these locations sustain the disease in nature. To date, heartwater has never been reported in Asia despite the presence of many species of *Amblyomma* ticks. The U.S. has two tick species, *A. maculatum* and *A. cajennense*, that have been shown experimentally to be capable of serving as vectors of heartwater.

Center for Food Security and Public Health Iowa State University 2006

> www.vet.uga.edu/vpp/gray_book. In areas where heartwater is always present (endemic), there has been evidence of transmission from infected cows to their calves through colostrum (oral). The ticks can also pick up infection from wild ruminants such as blesbok (*Damaliscus dorcas phillipi*) and black wildebeest, and wild birds like the cattle egret, helmeted guinea fowl, leopard tortoise (*Geochelone paradalis*) and scrub hare because these animals harbor the rickettsia *E. ruminantium* subclinically for long periods.

animal species- 3 to be exact, making them a three host tick. Ticks can acquire the infection from the host from the time the fever starts for up to 361 days, or longer. They become infected during larval or nymphal stages and transmit the organism to the subsequent life-cycle stage (transstadial transmission). They probably retain the infection for life.

Infected female ticks do not transfer the rickettsia to offspring (transovarial transmission). Photo from The Gray Book at

The peracute form of heartwater typically occurs in non-native breeds of cattle, sheep and goats introduced into an area where the disease is already present. Heavily pregnant cows are especially prone to develop the peracute form of the disease. Sudden death is the typical manifestation for this form. Clinical signs possibly seen prior to death may include fever, severe respiratory distress, and convulsions. Additionally, some breeds of cattle (Jerseys and Guernseys) may develop severe diarrhea. Clinical signs of the subacute form include prolonged fever and coughing due to fluid in the lungs- pictured right along with fluid in the chest cavity. Animals may show mild incoordination and either recover in 1-2 weeks or die. Photo from The

There are efforts to try and eliminate the tropical bont tick from the Caribbean so that heartwater will be less of a risk in those areas and in the U.S. Since 1995, a project carried out by the Food and Agriculture Organization (FAO) and national governments, and funded by the United States, the International Fund for Agricultural Development, and the European Union, has radically reduced the number of affected animals.
